

Doctor Clinical Report

Generated on: 2026-05-12 14:51:34

Clinical Support Report: Melanoma

Patient Information: (Not provided in the report)

Disease: Melanoma

Model Confidence: 30.03%

Lesion Metrics: Lesion area (pixels): 450712

Diagnostic Reasoning:

Based on the provided lesion metrics and the reference medical literature, the lesion in question is suspected to be melanoma. The ABCD criteria for identifying suspicious pigmented lesions (Asymmetry, Border irregularity, Colour variation, and Diameter) are not fully detailed in the provided information.

Possible Differential Diagnoses:

Given the lesion's characteristics, possible differential diagnoses include:

- Pyogenic granuloma: A vascular tumor that can be amelanotic and may be misdiagnosed as a melanoma.
- Squamous cell carcinoma (SCC): A type of skin cancer that can present with a similar appearance to melanoma.
- Benign melanocytic naevi: While melanomas can arise in pre-existing naevi, the lesion's size and irregular shape are more suggestive of melanoma.

Next Clinical Steps:

Given the suspicion of melanoma, the following next steps are recommended:

- Biopsy:** A biopsy of the lesion is essential to confirm the diagnosis of melanoma and to determine the depth of invasion.
- Dermoscopy:** Dermoscopy can provide additional information about the lesion's morphology and can help in identifying specific features suggestive of melanoma.
- Follow-up:** Regular follow-up appointments are necessary to monitor the lesion's growth and to detect any changes.

AI-Assisted Opinion:

This report is an AI-assisted opinion, and while the model has provided a suspected diagnosis of melanoma, it is not a substitute for a clinical diagnosis by a qualified healthcare professional.
